Well Digging

A guide to the construction and protection of hand dug wells.
Acknowledgements
This book is written in non-technical language. It describes how to dig and protect a well. It also describes how to improve and upgrade a traditional well.
Many people have assisted the author by providing valuable information for the book. In particular, mention should be made of the Public Health Inspectorate of the Ministry of Health, the staff of Blair Research Laboratory, non-Governmental organisations, and the teams of health and other workers who strive so hard to improve water supplies throughout Zimbabwe.
To the Health Education Unit of the Ministry of Health and many others not specifically mentioned, but who have so willingly supported this work - our thanks.
Finally, to GTZ, who have generously funded the development of this book, - our appreciation.

Sue Laver

Developed by Sue Laver for GTZ in collaboration with TAG/World Bank and the Ministry of Health, Masvingo Province. Illustrated by Kors de Waard.
Well digging

A guide to the construction and protection of hand-dug wells
Our book is about well digging.

It tells us how to

* join a well digging project
* dig a shallow well
* protect a shallow well
* improve a traditional well

Our book also describes what the community can do to maintain the well and use it hygienically after it has been completed.
Wells provide an important source of water to our people

Promote well digging at community level!

At this time in rural Zimbabwe, thousands of families depend on wells for their daily water supplies. Many of these wells are constructed by groups working together in the community. Others are built by their individual owners or experienced well diggers.

Water is essential to development and our Government supports the people's efforts to provide water to their families in this way. In promoting well digging at community level we should also promote methods of well protection, and help people to understand water hygiene too.

In this way water will come to be valued by our people as an asset to good health and development at community level.
We can promote well digging for these reasons.

* Wells can be constructed close to the home
* People in the rural areas of Zimbabwe can afford to build wells
* Wells are traditionally acceptable to the people of Zimbabwe
* Wells provide a place for natural water storage
* Most materials needed for well digging are available in the community
* There are skilled well diggers in many communities so there is no need to call outside experts
* Well digging is a group activity
* The quality of water in traditional wells can be improved and maintained by protection, good hygiene and careful maintenance

There can be disadvantages too.

* Some wells provide inadequate supplies of water because they are too shallow
* Shallow wells may dry up quickly after the rains
* Many wells are sources of hidden disease and danger because they are polluted
* Uncovered, unprotected wells are dangerous
It is important to combine education with well digging.

Why is it that some families who take their daily water supplies from wells commonly suffer from sicknesses such as diarrhoea and other health problems? These problems occur because their family water supply is polluted with disease-carrying germs. Sometimes the wells are far away from the homes. Sometimes they are shallow. When problems like these exist, the people do not collect enough water to use for daily hygiene activities. Then health problems such as sore eyes, skin infections and malnutrition occur. If the people do not collect enough water for growing food, then malnutrition may occur. Health problems also arise when people are careless about how they collect and store the water from their wells.

It is just as important to tell people about the causes of health problems as it is to tell them about good ways of digging wells. The people must understand the need

* to protect a well so that waste cannot enter the water
* to maintain the drainage area around the well so it does not become littered with rubbish and mud
* to fit a windlass or simple pump to raise water hygienically
* to collect and store water hygienically
* to provide plenty of water for body hygiene, use in the home and for projects such as growing food
* to improve sanitation in the community
Project information about well digging

All plans for water development projects in an area must be discussed with the VIDCO. Representatives of the VIDCO will help groups to reach decisions about their water projects. There are also other community-based workers such as Health Inspectors, Village Health Workers, Agritex workers and many more people who can share information about water projects. Groups also need to talk to key leaders and those who have dug traditional wells.

Before starting to dig the well, the project group needs to decide together with the community leaders:

* who will use the well
* who will dig the well
* who will pay for the well
* what materials and tools will be needed for digging the well
* how the group members will share the tasks
* how to protect the well
* how to raise clean water from the well either with a simple windlass or handpump
* how to make a drainage area around the well
* how to share the maintenance of the well

If a professional well digger is hired, the group should decide who will be responsible for providing food and shelter.
A well-digger needs materials and tools

Building materials

Cement for
* lining the well
* protecting the well
* building the drainage area

The amount of cement will depend on the depth of the well and the type of lining eg
* for a 5 m deep well which is lined with stones or burnt bricks, 5–6 bags of cement will be needed.
* for a well 5 m deep which is lined with concrete rings 13 bags of cement will be needed

Reinforcing wire
* use 8 gauge reinforcing wire for strengthening the cover slab

Stones
* large stones for lining the well and
* small stones for the concrete mix

River sand
* for the concrete mix

* In some parts of the country, steel moulds are available for making concrete well liners. In other places steel shutters are used for this task.

Tools
ladder trowel rope hammer
2 buckets tape shovel string
pick wooden float spirit level steel float
chisel pliers (for cutting wire)

A simple windlass can also be made to make the task of raising the rock and soil from inside the well easier as it is dug. Use strong poles, steel wire, a pulley and a bucket.

cement
burnt bricks
reinforcing wire (8 gauge)
rope
river sand

* The pliers are used for cutting wire
Step 1 Site the well

The decision to site a well is reached by the group who will share the water supply. They are assisted by the community workers and others such as traditional diviners who specialise in seeking water.
A good site for a well is

* 30 metres (100ft) uphill from the latrine or rubbish pit so that contaminated waste does not drain into the well.
* uphill and away from cattle kraals and from large hollows in the ground
* on one side from latrines, cattle kraals, refuse pits if there are no hills nearby
* on a rise so that waste water can drain away from the well into a garden
* in a place which is near the homes of all the users
* on a site which can be reached at all times of the year
* a site which provides sufficient water near to the home for the users at all times of the year.

Other natural signs such as trees (the muondo tree, the mukute tree) and grasses which grow only in wet places be also be used to find water.
Step 2 Mark out the circumference of the well

Decide on the finished diameter of the well (usually about 1.5 m (5 ft) if bricks or stones are used for lining).

Mark out the well

To do this

* cut a piece of string which is the same length as the diameter of the well
* place a peg in the ground
* loop the string around the peg
* use the string as a guide, and mark out the circumference of the well
Safety rules for well digging

Well digging can be dangerous.

Follow these rules for safety.

1. The best time to dig a well is at the end of the dry season. It is the safest time and the underground water level is at its lowest.

2. Tell the group when digging is being done.

3. Always have a helper nearby when digging. NEVER DIG ALONE.

4. Stop digging at once if any signs of collapse are noticed.

5. Cover the hole when digging is not in progress. This will prevent children or animals falling inside. Do this with strong poles or branches from thorn trees.
Step 3  Begin to dig

Keep the same diameter from top to bottom **
Keep the sides straight
Remove soil from inside the well as it is dug.

Safety rules

1. Cut steps in the sides of the well so that the well digger can climb out easily when he needs to.
2. Stop digging if the sides of the well begin to crumble and show signs of collapse.

** Important: Some well diggers like to make the diameter smaller (1.2 m) when they reach harder ground. This is fine.
**Step 4** Continue to dig even when water is first reached.

When water is first reached
* remove water and mud quickly. Use two buckets to do this
* continue digging until hard rock is reached and at least 50 litres of water is removed over 2 days. This means there will be enough water in the well for the needs of a large group of users.

**Safety rule**
When water is reached, extra helpers are necessary. They can assist the well digger to remove mud and water from inside the well.
Step 5  Line the well

All wells except those which are cut or blasted through solid rock, should be lined using burnt brick, cement bricks, stones, concrete well liners or concrete.

The lining is important because
* it protects the well by reducing pollution from seepage
* it protects the water from soil
* it prevents collapse of the sides
* it helps to make the well last longer

One or more methods can be combined to line a well. In areas where there is hard rock or the soil is stable, line only the top half of the well.

<td></td>
<td>* Cement is expensive</td>
</tr>
</tbody>
</table>

* These are made using steel ring moulds which are available in some parts of the country.
** In some areas the lining is made of concrete. Well diggers use steel shutters for this task.
The well is lined from the bottom except where there is solid rock. In such cases the well is lined for only 2–3 metres near the top. All well linings are raised to a height of at least 30 cm above ground level.

**Note:** It is usually necessary to backfill when lining the last three metres of the well. Backfill is always used when improving and lining a traditional well.
Step 6 Make a raised collar for the well

To make a raised collar build the well lining above ground level.

The lining must be raised at least 30 cm (1 ft) above the ground.

This

* prevents run off water from spilling back into the well
* prevents erosion at the edges of the well
* provides a strong foundation for the cover slab.

Note: Backfill around the brick collar to prevent erosion of the soil.
Step 7 Prepare a protective cover slab for the well

A concrete cover slab for the well can be made in one or two pieces. An opening is made in the slab through which a bucket or pump can be passed into the well. The finished cover slab will rest on the raised collar of the well.

The cover slab is important because it
* prevents waste water draining into the well
* protects the well, prevents things from falling into the well and makes it safer for children
* provides a safe resting place for a pump
* is long-lasting
* is easy to build and maintain

To do this

* clear and level a place close to the well
* estimate the diameter carefully. This should include the width of the cover slab, the brick or stone or cement lining and the backfill area. Allowance is also made for the overhang. Use string or tape to do this
* mark out the diameter carefully
* use bricks to mark the edges of the mould
* lay old plastic bags or sand inside the mould so that the slab does not stick to the ground when it is completed

Build according to instructions
**Step 8** Make the protective cover slab

Pour a 17 cm layer of concrete around the tin or brick templates inside the mould. Cut reinforcing wires and lay 30 cm apart (or use one inch chicken wire) on top of the concrete layer.

Pour the remaining concrete mix on top of the reinforcing wires. Smooth off with a wooden float.

The finished slab is 15 cm (3 inches) thick when completed.

Cover with wet sacks and leave to dry for 3-5 days before moving.

---

**Concrete mix:**
- 1 part cement
- 4 parts stone chips
- 2 parts sand

**Old tin to mould an opening in the slab for the bucket**

**Plastic bags**

**Reinforcing wire (8 gauge)**

**Rings (made from reinforcing wire) for easier lifting of the slab**
A protective cover slab can also be made in two pieces

If possible, it is better to make the cover slab in two pieces. This is because

* it may become necessary to inspect the well or raise the pump fittings. It is simple therefore to move over one part of the cover slab.
* it is easier to lift the cover slab onto the collar if it is made in two pieces
* a slab of two pieces is stronger and there is less risk of cracking

Concrete mix:
1 part cement
2 parts sand
4 parts stones

Old tin to mould an opening in the slab for the bucket

Cut the wire to size

Reinforcing wire

Plastic bags

Rings for easier lifting of the slab

* divide the mould with bricks as shown in the pictures
* have an old tin or templates ready to mould an opening in the slab for the bucket or pump. The size of the opening should be larger than the bucket normally used by the group to raise water.
Step 9 Lift the cover slab into position over the well

The cover slab is positioned on the raised collar above the well. Extra help is needed for this task.

The cover slab is mortared onto the raised collar.
These diagrams show the different methods recommended for raising water from a well after the cover slab is fitted.

A Blair hand pump is fitted to raise water from shallow wells (12-15 m) and tube wells.

A bucket pump will also raise water from shallow wells and tube wells.

For more information about how to fit these pumps ask for the Pump Handouts.

The Bush pump is a heavy duty pump which is used to raise water from shallow wells and deep wells.

In shallow wells a windlass can be used to raise water. This method is described on pages 28-29 of this book.
Step 10 Complete the well and make a drainage area too

The drainage area (also called the apron and run-off channel) is important because it

* helps waste water drain from the well quickly and easily
* prevents stagnant water from collecting around the well
* prevents erosion around the top of the well
* channels waste water into a garden or watering trough
* keeps the well area free from mud and easy to clean

To complete this task

* measure a 3 m diameter circle around the well
* mark the edge of the circle with stones or bricks
* backfill the area between the bricks and the well with smaller stones or broken bricks
* cover these with concrete and reinforce with steel wire to prevent cracking
* smooth the concrete surface of the apron
* slope a 10 m long run-off channel towards a soak away pit, vegetable garden or animal watering trough
Improving a Traditional Well
The need to improve Traditional Wells

There are thousands of traditional wells throughout Zimbabwe. Many are badly sited. They are far from the home and the user must walk long distances to collect water for their daily needs. Some traditional wells are downhill from community cattle kraals, latrines and rubbish pits so that disease carrying germs easily drain into the wells. Where the traditional wells are unprotected, badly sited, in danger of collapse or provide too little water, it is better for groups to build new wells. If the traditional well is near to the homes of the users, correctly sited and provides adequate water at all times of the year, then it is better to improve the supply.

When combined with education about hygienic practices for collecting and storing water the group will benefit from their efforts to raise better quality water.

The quality of water in traditional wells can be improved by following the simple steps described in this book.
Traditional wells can be improved through group effort
How to improve a Traditional Well: step by step

Efforts to improve a traditional well will be rewarded if each task is done properly. Follow these steps carefully.

Step 1  Clean and deepen the well
Remove mud, stones and rubbish
Make the well deeper if possible

Step 2  Line the well and backfill
Below water level: stack rock on the sides of the well. Do not use cement mortar
Above water level: line the well with burnt bricks or stone. For this use cement mortar
Backfill with layers of gravel, cement and puddled clay between the old wall and new lining
Look at the picture on page 27 for more information about lining

Step 3  Raise the new lining 30 cm above ground level to make a collar
To do this follow the instructions on page 16

Step 4  Make a protective cover slab
To do this follow the instructions on page 17

Step 5  Fit a pump or windlass to raise water
Note: If a pump is chosen, follow the step-by-step instructions in the Pump Handouts. If a windlass is chosen turn to page 28

Step 6  Make a hygienic drainage area around the well
To do this follow the instructions on page 22
Method for fitting a windlass to a Traditional Well

1. After the cover slab is positioned over the well, make a protective collar around the opening of the well

Cement mix:
1 part cement
8 parts sand

2. Make holes for the windlass supports

Concrete mix:
1 part cement
2 parts sand
4 parts stones
3. Fit the windlass

Now complete the project and build a drainage area around the well

Cement mix:
1 part cement
3 parts sand
Water hygiene

Even if a well is properly maintained with a protective slab and a good drainage area, the water inside the well can be contaminated if the people do not use hygienic practices for collecting and storing water. Water hygiene is important!

Encourage users to

* collect their water in clean containers
* store their water in clean covered containers
* wash their hands frequently
* make a hook on the windlass on which to hang the bucket when it is not being used
* keep the rope or chain off the ground so that it does not get dirty
* replace the protective cover over the well when the windlass is not in use
* keep the drainage area free from dirt and mud
* keep animals away from the area
* teach hygienic practices to children (as they will very often be collecting the water)
* maintain the pumps so that water can continue to be raised hygienically
* use more water for body hygiene
* use water for other development projects, such as growing food for the family

Good sanitation is important too!

Encourage people to support latrine building projects in the area.
Raising water with different pumps

Pump handout No 1
The Zimbabwe Bucket Pump

The Zimbabwe bucket pump is a hand operated pump which is used to raise water from tube wells and hand dug wells in rural Zimbabwe. Bucket pumps provide a simple, safe and hygienic way of raising water for domestic use. Bucket pumps are made in Zimbabwe. They can be easily installed by the community and will last for many years if properly maintained.
The bucket pump, how it works

- The bucket pump is installed over a tubewell or a shallow handdug or blasted well.
- The bucket, the steel head and cap, the windlass and the windlass supports are made of steel.
- The wooden bearings are made of hard wood.
- The bucket is lowered into the well on a steel chain which is attached to the windlass.
- The bucket is raised by the operator who winds up the chain, using the windlass handle.
- The operator rests the bucket on the water-discharger. The valve inside the bucket opens and water is released into a water-container.
Different materials are needed for fitting a bucketpump to a watersupply.

These tools are provided with the bucketpump. Check them!

- Hacksaw
- Short socketspanner
- Flat spanner
- Long socketspanner

Materials needed for fitting the bucketpump:

- Building sand
- Cement (appr. 4 pockets)
- Rocks for building the drainage area
- 12 x 5 ltr buckets full of small granitechips or sieved coarse river sand
- 125 mm PVC casing class 6
FIT A BUCKET PUMP

STEP BY STEP

A bucket pump raises clean water from underground. A tubewell is drilled by the community using a hand operated drilling rig. The well is lined with 125 mm Class 6 PVC casing to prevent collapse. Then the bucket pump is fitted. A drainage area is built around the well. To assist, the community can bring:
- sand & stones
- small gravel chips

Class 6 PVC casing & cement is also required.

1. After the tubewell is drilled, make a gravel bed at the base.
   Use two 5 litre buckets of gravel chips.

2. Lower lengths of (Class 6) PVC casing inside tubewell.
   Hold casing upright and straight.

3. Pack gravel chips around PVC casing.

4. Pack concrete around top metre of casing inside tubewell.

Leave 1 metre for concrete at the top of tubewell.

Concrete mix:
4 stone: 2 sand: 1 cement.

Mix concrete.
5. Use a saw to cut PVC casing off 30 cm above ground level.
   - Measure carefully.
   - Cut straight.
   - Then cover PVC casing with plastic to prevent dirt falling into tubewell.

6. On each side of the tubewell, dig holes for the bucket pump supports.

7. Position the bucket pump.
   - Fit steel cap over casing.
   - Lower pump supports into holes.
   - Level pump so it is upright.
   - Backfill with concrete mix 4:2:1.

8. Build a drainage area around bucket pump.
   - To do this, measure a 3 m diameter circle around bucket pump.
   - Mark with stones.
   - Use concrete mix 4:2:1.
   - Backfill drainage area.

9. Make a runoff channel to garden.
   - Slope drainage area to runoff channel.
   - Leave to dry for 3 days.

10. Now the pump is ready to use.
    - Adjust chain carefully so that bucket does not hit base of tubewell.

Extra information
about maintaining and making minor repairs to the bucket pump.

1

Secure the chain on the barrel of the windlass like this
Then wind the chain onto the windlass. Inspect the chain to see that it is not worn or rusted. Replace if necessary.

2

Secure the chain to the bucket:
- Use a nut and a bolt to do this.
- Wire can also be used for this task if necessary.

- Adjust the chain to prevent the bucket from hitting the base of the tubewell!
- Advise the people to take care when using the windlass.
The bucket

The bucket valve is inside the bucket

To replace the washer:
- Remove the splitpin
- Use the long spanner to secure upper nut
- Use short socket spanner to unscrew the lower valve nut

- Remove grit or stone which may have collected between the washer
- Check the washer, replace if necessary
- Secure the nuts, using both spanners
- Replace the splitpin

Raising water with different pumps

The Zimbabwe Blair Pump

The Blair Pump is a simple hand-operated pump which is used to raise water from shallow wells and tube wells around 12-15 metres deep. It is best suited for family or small group use, is affordable, easy to install and simple to operate. The working parts of the Blair Pump are made from galvanised iron and PVC (which is hardened plastic tubing of a certain size). A tool kit and a maintenance kit is supplied with the pump. Spare parts are also available, and if the pump is carefully maintained it will give good service to its users for many years.

The Zimbabwe Blair Pump was developed at Blair Research Laboratory, Harare.

Developed by Sue Laver for GTZ in collaboration with TAG/World Bank and the Ministry of Health, Masvingo Province. Illustrated by Kors de Waard.

Instructions for making and fitting the Blair Hand Pump

A Blair Pump is assembled and fitted in different stages.

1. A concrete headblock is prepared

2. The concrete headblock is fitted over the well slab or tube well

3. The depth of the well is measured carefully

4. The working parts of the Blair Pump are joined together

5. The assembled pump is lowered into the well and screwed tightly into the concrete headblock. The Blair Pump is then ready to use.

To do this follow each step carefully
Step 1 Prepare the concrete headblock

A concrete headblock is sometimes supplied with the Blair Pump, or it can be made. The headblock is fitted onto the well slab or tube well before the pump is installed.

To make a concrete headblock

* Use a plastic basin or similar container as a mould
* Stand the pump socket in the centre of the mould
* Make a concrete mix:
  1 part granite chips
  1 part washed river sand
  1 part cement
* Pour the concrete mix around the pump socket and press down firmly
* Add reinforcing wire cut to size for extra strength
* Make sure that the pump socket is level and straight. It should rise 6 mm above the level of the concrete mix
* Cover with wet sacks
* Leave to set for at least one week

Follow instructions carefully!
Step 2  Position the concrete headblock over the water supply

In shallow wells

The concrete headblock is lifted over the well slab and mortared in position. The pump socket inside the headblock must lie directly above the opening in the well slab.

In tube wells supplied with headblock

Follow these steps so that the headblock is correctly positioned

Measure the depth of the pump socket hole in the concrete headblock (approx 10cm/4inches)

Record this measurement on the PVC casing

Cut the PVC casing to size

Lay cement mortar around the PVC case. Use a spirit level to position the headblock correctly. The PVC casing must fit centrally inside the headblock.
Step 3  Measure the depth of the well carefully before joining up the working parts of the Blair Hand Pump

Before the working parts of the pump are assembled, measure the depth of the well. Use the string with a weight on the end to do this. Measure from the top of the concrete headblock to the base of the well.

Now cut 50 cm off the total length of the string.

Lay the string and the working parts of the Blair Pump out side by side on the ground (see diagram on page 2)
Follow instructions for assembly
Step 4  Assemble the working parts of the Blair Pump

To do this:

A. Connect galvanised iron pump handle to PVC pushrod connector. (see diagram on page 2)

To do this:
* Check that the spring and handle guide are in position
* Glue inside of PVC pushrod and outside of pump handle connector with Trinepon 6 Quickset Glue
* Screw pump handle into PVC pushrod tightly

Follow these instructions for glueing together parts of the pump

* Clean all surfaces thoroughly before glueing
* Apply glue to the end of each joint to be connected
* Use a screwing action to join working parts
* Wipe off waste glue
* Leave the parts to dry for at least fifteen minutes
* Replace top on glue when task is completed
* Store glue away from heat
B. Join galvanised iron headblock to PVC cylinder (see diagram on page 2)

* Use PVC Cement for this task
* Clean joint ends thoroughly
* Clean away extra glue
* Leave to dry

C. Join PVC cylinder at footvalve end

D. Make final cylinder join using a connector

To do this:
* Measure the cylinder length exactly as shown in the picture

When completed, the PVC cylinder is exactly equal in length to the string used to measure the depth of the well. (Remember that the string was shortened by 50 cm in Step 3)

The number of connectors depends on the depth of the well.
E. Make the pushrod

To do this:
* Push the handle guide against spring of pump handle
* Line up pushrod with cylinder exactly as shown in the diagram

It is very important to do this exactly as shown.

Depending on the depth of the well, you may need to use several PVC connectors to join together lengths of PVC pushrod. Use PVC glue to make the final joins.
Step 5  Fit the pump into the water supply

A. Fit the PVC cylinder through the concrete headblock into the well

To do this:

* Remove footvalve using the spanner supplied
* Wash the footvalve thoroughly
* Pour water through the cylinder, turning it slowly to make sure that all dirt is removed
* Replace footvalve and screw tight with the spanner
* Fit the cylinder into the well
* Screw the pumphead into the concrete headblock
* Tighten with spanner

B. Fit pushrod through the cylinder

To do this:

* Remove and wash piston and piston valve
* Replace piston and piston valve
* Install pushrod by lowering it into the cylinder
C. Fit the two halves of the nylon bushes around the pushrod inside the headblock

To do this:

* Place 2 halves of nylon bush round top of pushrod
* Slide the handle guide over this and screw tightly into pump headblock
* Before tightening, test the pump. If the handle does not move freely up and down, unscrew the metal guide, change the position of the nylon bushes refit metal guide
* Test again.
* Tighten with spanner
Extra information about maintaining and making minor repairs to the Blair Pump

To repair or change length of PVC pushrod or cylinder:

1. Saw the broken ends.
2. Apply PVC-cement to end of pipe and inside connector.
3. Push connector on to pipe with a twist.
4. Apply PVC-cement inside connector and to end of pipe.
5. Push pipe into connector with a twist.
